VULTURE BEES

In the forests of Central and South America, scientists have discovered a very different kind of bee. This strange bee does not feed on pollen and nectar as most other bees do. Instead, it gobbles up the flesh of dead snakes, anteaters and other forest creatures. When these bees feed, they spit out a special chemical called an enzyme. This enzyme changes the dead animals' flesh into a gooey, chewy mush. The bees eat the mushy meat and store it in their special "meat" stomachs.
